

What does the power of photovoltaic panels depend on

Overview

Output depends on sunlight, temperature, shading, orientation, and system design. Two panels with the same wattage can have very different energy output based on installation conditions. A photovoltaic (PV) cell, commonly called a solar cell, is a nonmechanical device that converts sunlight directly into electricity. Sunlight is composed of photons, or particles of solar energy. Different solar panels have varying voltage ratings, typically ranging from 12V to 48V. 12V panels are often used for small solar setups because they are compatible with 12V. A panel's rated watts (also called its solar panel rating) help estimate how much power it can produce, how many panels you may need, and how your system might perform over time. The PV cell is composed of semiconductor material; the “semi” means that it can conduct electricity better than an insulator but not as well as a good. At a high level, solar panels are made up of solar cells, which absorb sunlight. There are two forms of energy generated from the sun for our use – electricity and heat.
